

SESSION 1 — ACTIVITY (Decode the Chart)

Name: K Sasi Rekha

Roll no: 33

For each chart below, answer: What is it trying to tell you? Do you trust it? Why or why not?

Chart 1

Market Share by Product (9 categories)

Chart 2

Chart 3

Chart 4

Chart 1: Regional Comparison

- **What it is trying to tell you:** It compares revenue across four cities (Kanpur, Delhi, Vizag, and Madurai), suggesting large differences in performance between regions.
- **Do you trust it?** No.
- **Why or why not?** The vertical y-axis (Revenue) is truncated—it starts at 850 instead of 0. This visual distortion makes small differences (e.g., ~859 Cr vs ~879 Cr) look huge, making Vizag appear as though it achieved double or triple the revenue of Madurai.

Chart 2: Market Share by Product (9 categories)

- **What it is trying to tell you:** It shows the proportional market share distribution across 9 different product categories using a pie chart.
- **Do you trust it?** No.
- **Why or why not?** Pie charts are notoriously difficult to read when split into too many slices (9 categories). Without explicit numerical percentages or labels on each slice, it is nearly impossible to distinguish similar-sized slices or accurately compare categories.

Chart 3: Ice Cream Sales vs. Drowning Incidents

- **What it is trying to tell you:** It implies a direct relationship or link between higher ice cream sales and an increase in drowning incidents over time.
- **Do you trust it?** No.
- **Why or why not?** This suffers from a classic "Correlation does not imply causation" fallacy (spurious correlation). Both variables increase together due to an unmeasured third factor (a confounding variable, such as warm summer weather/seasonality), not because buying ice cream causes drowning.

Chart 4: Study Hours vs. Exam Score

- **What it is trying to tell you:** It plots study hours against exam scores to see if more study time leads to higher grades.
- **Do you trust it?** No (as a meaningful/logical dataset).
- **Why or why not?** The scatter plot shows a completely random "blob" with zero correlation ($r \approx 0$). In reality, study hours typically correlate positively with exam scores, but this data shows people studying 80+ hours scoring the same on average as those studying 0 hours, indicating unreliable or synthetic data.
